Shocks in the Ramsey Model

Unexpected permanent shocks

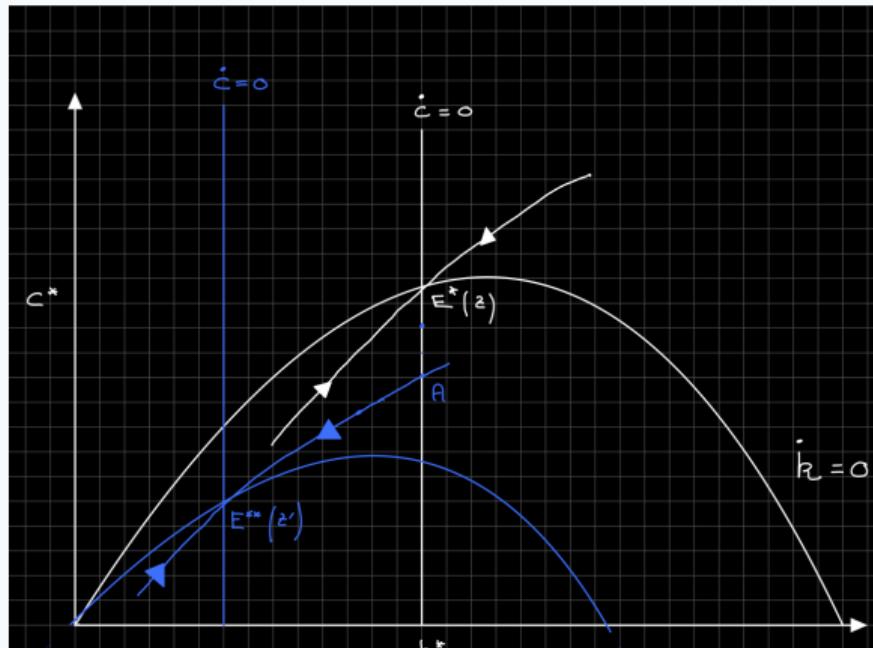

Consider a permanent shock to TFP so that z decreases to z' in period 0.

In this case the competitive equilibrium dynamics correspond to the dynamics of the economy with TFP z' from $[0, \infty)$.

The economy immediately transitions to the new steady state dynamics.

Unexpected Permanent Shocks

Phase diagram analysis

Unexpected Permanent Shocks

Solution path and dynamics

The solution path is:

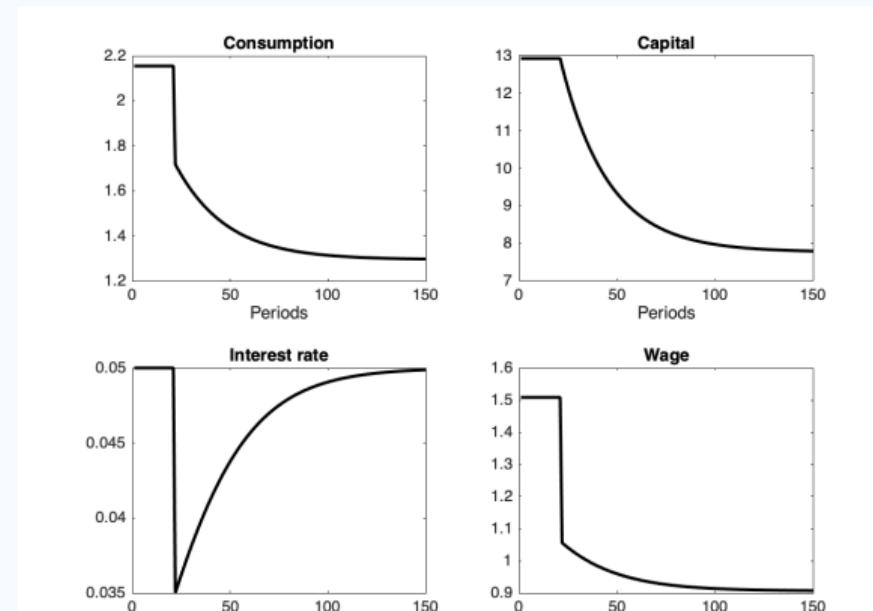

$$E^* \rightarrow A \rightarrow E^{**}$$

- ▷ Consumption jumps down to A at the shock
- ▷ Then consumption continues to decrease with capital along the saddle path for the blue dynamics
- ▷ Economy converges to new steady state E^{**}

Unexpected Permanent Shocks

Time series dynamics

The negative shock happens at $t = 0$ and is permanent.

Unexpected Temporary Shocks

Setup and timing

Consider a temporary shock to TFP so that z decreases to z' from period 0 to period T .

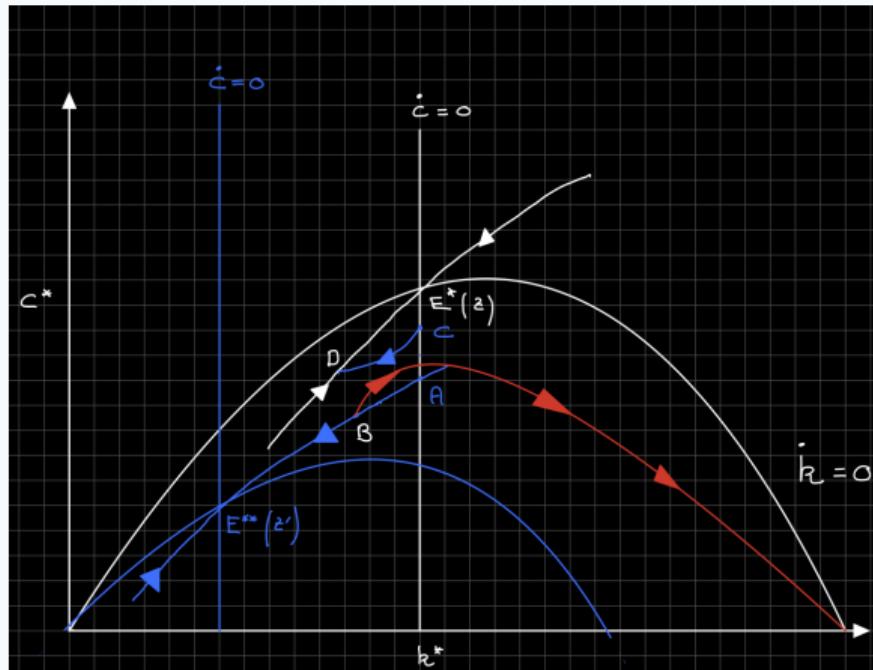

In this case the competitive equilibrium dynamics correspond to:

- ▷ Economy with TFP z' from $[0, T)$
- ▷ Economy with TFP z from $[T, \infty)$

The challenge: ensuring continuity at time T when shock ends.

Unexpected Temporary Shocks

Phase diagram analysis

Unexpected Temporary Shocks

Solution path and dynamics

The solution path is:

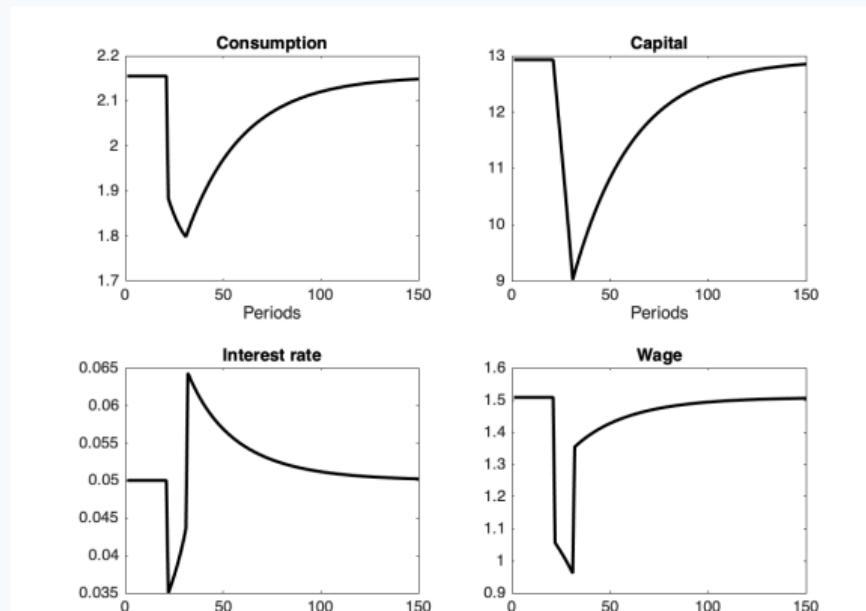

$$E^* \rightarrow C \rightarrow D \rightarrow E^*$$

- ▶ Consumption jumps down to C at the shock
- ▶ Economy follows explosive path $C \rightarrow D$ under blue dynamics
- ▶ Path $C \rightarrow D$ is the **only** explosive path that crosses point D at time T
- ▶ At time T , economy jumps to saddle path returning to E^*

Unexpected Temporary Shocks

Time series dynamics

The negative shock happens at $t = 10$ and lasts until $t = 20$.

Unexpected Temporary Shocks

Why not jump to point A?

Consider the alternative path where the initial jump would go to A:

- ▷ This would be the solution after a **permanent** shock
- ▷ Economy would be on the saddle path that goes to E^{**}
- ▷ However, at time T the economy would be at point B
- ▷ From there it would follow an **explosive path** under the original equilibrium

This solution violates transversality conditions — phase diagrams help visualize this constraint.

Permanent Expected Shocks

News shocks and anticipation

Consider a different shock where agents expect z to increase in T periods.

- ▷ Agents react immediately to the "news" shock
- ▷ The solution requires that they find themselves on the final saddle path at time T
- ▷ Forward-looking behavior creates immediate adjustments

Permanent Expected Shocks

Solution path — Case 1

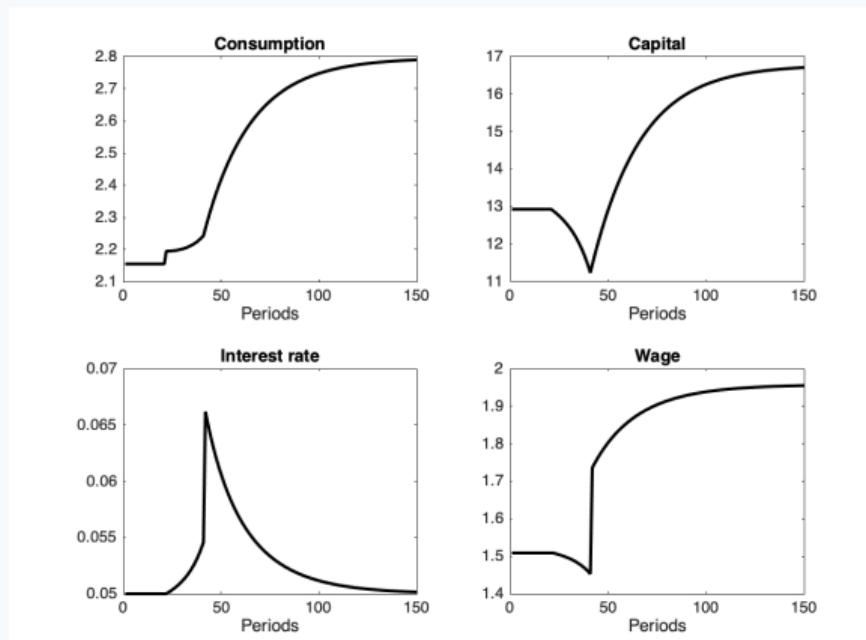

The solution path is:

$$E^* \rightarrow A \rightarrow B \rightarrow E^{**}$$

- ▷ Consumption jumps to A immediately upon news
- ▷ Follows the unique explosive path that crosses the green saddle path at time T (point B)
- ▷ After time T , follows saddle path to new steady state E^{**}

Permanent Expected Shocks

Time series — Case 1

Permanent Expected Shocks

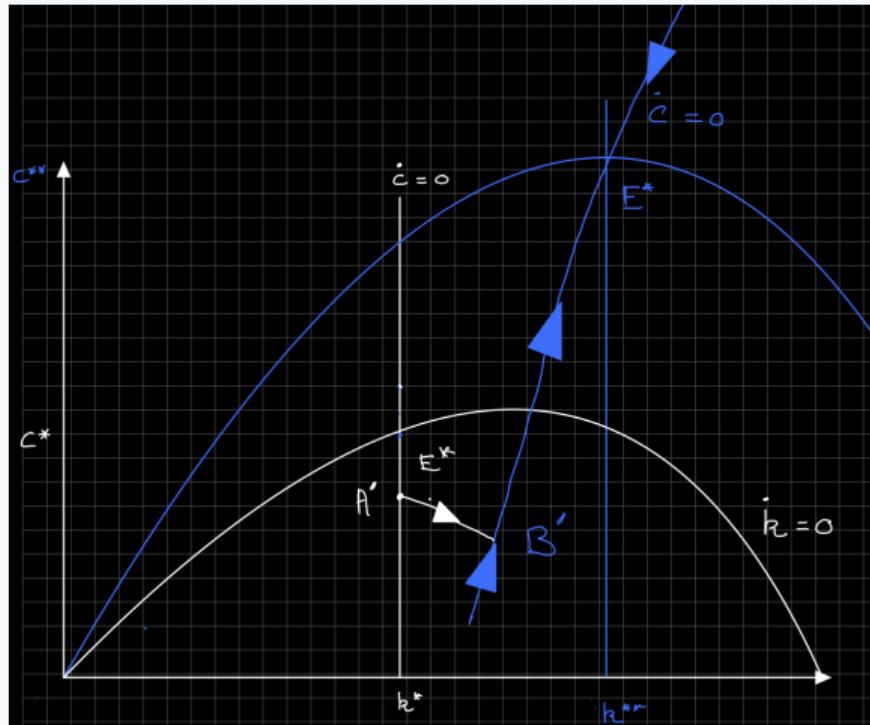

Alternative case with high substitution

Note that there could be another solution: with very high intertemporal substitution, the saddle path would be very steep.

- ▷ Consumption would fall initially
- ▷ The adjustment would be much faster
- ▷ Different slope of saddle path leads to different dynamics

Permanent Expected Shocks

Phase diagram — Case 2

Permanent Expected Shocks

Time series — Case 2

In this second case the endogenous variables have the following dynamics:
